approximated the geometry by two conducting infinite half planes and investigated the trajectories of a positive ion emitted at some point on the positively charged infinite half plane with given initial velocity and a given direction of emission.

## I. INTRODUCTION

The work reported in this note was done for the purpose of determining the feasibility of neutralizing the potential difference that occurs on a spacecraft. It has been proposed that neutralization can be accomplished by emitting ions from the positively charged surface region of the spacecraft and by letting this current impact on the negatively charged surface region. In order to investigate the main features of the proposed scheme, we made some simplifying assumptions about the geometry of the problem. We approximated the geometry by two conducting infinite half planes and investigated the trajectories of a positive ion emmitted at some point on the positively charged infinite half plane with given initial velocity and a given direction of emission.

## II. MATHEMATICAL STATEMENT OF THE PROBLEM

We consider the plane y=0 and assume a cut on this plane along the z axis. Let there be a given potential difference V between the two half planes x > 0 and x < 0.

The equations of motion of a charged particle in the electric field produced in such a configuration are

$$m\frac{d^2x}{dt^2} = -\frac{eV}{\pi} \qquad \frac{y}{x^2 + y^2}$$

$$m\frac{d^2y}{dt^2} = +\frac{eV}{\pi} \qquad \frac{x}{x^2 + y^2}$$

$$m\frac{d^2z}{dt^2} = 0$$
(1)

The motion of the particle in the z direction is given trivially by

$$z = v_{z_0}t + z_0$$

where  $v_{z_0}$  is the initial velocity and  $z_0$  is the initial position in the z direction. The x-y motion in the x-y plane is on which we focus. No analytic integral even of this simplified model equation could be found.

We can make use of the two (energy and angular momentum) integrals

$$\frac{1}{2m}((\frac{d^2x}{dt})^2 + (\frac{dy}{dt})^2) - \frac{eV}{\pi} tg^{-1} \frac{y}{x} = \frac{1}{2m} (v_{xo}^2 + v_{yo}^2)$$

$$y\frac{dx}{dt} - x\frac{dy}{dt} + \frac{ey}{m\pi}t = x_0 \psi_{y0}$$
 (2)

where the initial velocities of the particle are  $v_{x_0}$  and  $v_{y_0}$ , and the initial position is  $x = x_0$ , y = 0.

In polar coordinates

$$x = r \cos \theta$$

$$y = r \sin \theta$$

the equations of motion become

$$(r\theta - r\dot{\theta}^2) \cos \theta - (2r\dot{\theta} + r\ddot{\theta}) \sin \theta = -\frac{\beta}{r} \sin \theta$$

$$(2\dot{r}\dot{\theta} + r\theta) \cos\theta + (\ddot{r} - r\dot{\theta}^2) \sin\theta = +\frac{\beta}{r} \cos\theta$$
 (3)

with

$$\beta = \frac{eV}{m\pi} \tag{4}$$

These equations can be combined into

$$2 \dot{r} \dot{\theta} + r \ddot{\theta} = \frac{\beta}{r} \tag{5}$$

and

$$\ddot{\mathbf{r}} - \mathbf{r}\dot{\theta}^2 = 0 \tag{6}$$

Eq. (5) can be simplified to

$$\frac{\mathrm{d}}{\mathrm{d}t}(\mathbf{r}^2\dot{\mathbf{\theta}}) = \mathbf{\beta} \tag{7}$$

which provides the angular momentum integral

$$r^2 \dot{\theta} = r_0 v_{yo} + \beta \quad 1 \tag{8}$$

Eq. (6) shows that r > 0 always, thus if  $r(0) \ge 0$ , r itself also increases all the time.

The energy integral is obtained from (6) through multiplication by  $\dot{\mathbf{r}}$ , and using (7):

$$\frac{1}{2}(\dot{r}^2 + r^2\dot{\theta}^2) - \beta\theta = \frac{1}{2}\nabla_0^2$$
 (9)

$$v_0^2 = v_{x_0}^2 + v_{y_0}^2$$
,

$$r_0 = x_0$$

Eliminating  $\dot{\theta}$  from (6) with the aid of (8), we obtain a second order differential equation for r:

$$\frac{d^2r}{dt^2} = \frac{(\beta t + r_0 v_{y0})^2}{r^3} \tag{10}$$

which becomes

$$\frac{d^2f}{du^2} = \frac{u^2}{f^3} \tag{11}$$

after making the transformation

$$u = \beta t + r_{o} v_{yo}$$

$$f = \sqrt{\beta} r \qquad (12)$$

A second order differential equation for the angle  $\,\theta\,$  can also be obtained, although it is of limited interest only:

$$\left(\frac{d\theta}{du} - u \frac{d^2\theta}{du^2}\right)^2 = 4u\left(\frac{d\theta}{du}\right)^3 \left(2\left(\theta + \frac{1_2v_0^2}{\beta}\right) - u \frac{d\theta}{du}\right)$$
 (13)

The differential equation of the trajectories can be obtained by eliminating t (or u). From (7) we have

$$r^2\dot{\theta} = \frac{d}{d\theta} (r^2\dot{\theta}) = \frac{1}{2} \frac{d}{d\theta} (r^4\dot{\theta}^2) = \beta r^2$$
 (14)

Eliminating  $\dot{\theta}$  with the aid of (8), this results in

$$f^{2} = \frac{d}{d\theta} \left( f^{4} \frac{\theta + \frac{\mathbf{1} \mathbf{y} \mathbf{v}_{0}^{2}}{\theta}}{f^{2} + \left( \frac{df}{d\theta} \right)^{2}} \right)$$
 (15)

## III. NUMERICAL SOLUTIONS

The equations of motion (1) can be cast in a dimensionless form

$$\frac{d^2x}{dt^2} = -\frac{y}{x^2 + y^2}$$

$$\frac{d^2y}{dt^2} = +\frac{x}{x^2 + y^2}$$

with the initial conditions that at time t=o

$$x = 1$$

$$y = 0$$

$$v_{x} = v_{x0}$$

$$v_{y} = v_{y0}$$

where the initial velocities  $v_{xo}$  and  $v_{yo}$  are in units of  $\sqrt{\beta}$ ,  $\beta = \frac{eV}{m\pi}$ .

We solved numerically this set of differential equations with the help of a subroutine DHPCG based on the Hamming's Modified Predictor Corrector Method. We assumed various initial conditions for  $v_{xo}^{}$ ,  $v_{yo}^{}$ .

In the Table we give some results for cases where there is no initial velocity in the perpendicular direction, that is  $v_{yo} = 0$ , and the inital horizontal

motion is towards the center. Also  $v_{z_0} = 0$ .  $x_{\star}$  is the distance, from the center, of the point where the positive ion impacts on the negatively charged half plane.  $y_{max}$  is the maximum value of the y coordinate of the particle along its trajectory. Note that our results, up to  $-v_{x_0} = 3.5$  are smooth in the sense that as  $-v_{x_0}$  increases,  $x_{\star}$  decreases. At  $-v_{x_0} = 4$ , and higher values, the results are not reliable. Whether the problem is in the numerical procedure is not clear at the present time.

Fig.-s 1, 2, and 3 portray families of particle trajectories with different initial conditions. In Fig. 1, the initial velocity is in the x-direction. It is clear that as  $\mathbf{v}_{x0}$  increases, the impact distance,  $\mathbf{x}_{x}$  is drastically reduced. Whether there is an optimum initial velocity, corresponding to a minimum impact distance, cannot be determined before the computational problem referred to above, is clarified. In Fig. 2, the initial velocity is in the y-direction. Here the impact distance increases with increasing velocity. In Fig. 3, the absolute value of the initial velocity is kept constant, while the direction of the emission is varied. There is a critical angle,  $\theta_0$ , at which the impact distance is the same as for  $\mathbf{v}_0 = 0$ . For  $\theta < \theta_0$  the impact distance is reduced, for  $\theta > \theta_0$  it is increased. With the chosen  $\mathbf{v}_0 = 0.1$ ,  $\theta_0 \approx 83^\circ$ . Figs. 4, 5, 6 give a more detailed picture of the dependence of the impact distance and of the maximum height of the trajectory on the parameters.
